Encom Releases Firmware Update 5.4.0 for HARMONY Product Line

Encom announces the release of the latest firmware update for its HARMONY line of radios. This update enhances and extends the functionality of the devices with the following new features:

- Any input at any device within the system can now control one or more outputs within the entire system, transmitting contact closure information and receiving feedback either through an IP network or using the optional 900 MHz radio.
- Using the new “Network Mode” feature in our COMMPAK I/O8 & I/O4 units, information can be transferred back and forth to the HARMONY IP I/O8 master inputs and outputs in real time. This information can be simultaneously monitored or overridden by our STRATOS I/O or STRATOS ELITE software through any network infrastructure available locally or onsite.
- Simple Network Management Protocol (SNMP) is a widely used protocol for remotely managing and monitoring devices and their functions. It enables devices connected to the network to relay management information within local (LAN) or wide area networks (WAN). This firmware release adds SNMP support and further expands the already long list of capabilities of the Encom HARMONY line of products. You can now connect a HARMONY device to any existing system including SCADA, Internet of Things (IoT) and even security monitoring applications, to name a few. Users can keep using whatever existing management software to monitor and control any Encom HARMONY device without sacrificing performance and reliability.

A technical bulletin for this update is available from our website at:
